<tr>
<td><strong>Abstract:</strong> Background: Falls are one of important cause of injury morbidity. Knowledge is limited about fall-related injuries in low- and middle-income countries in general and in Iran in particular. This study aims to document the epidemiology of injuries among rural community and to determine how fall injury control and prevention are conceived by community health workers (known as Behvarzes), given the role that they are expected to done for promotion of local people health and safety.</td>
</tr>
<tr>
<td><strong>Methods:</strong> The study was a six-month prospective injury data collection (from July 15th 2007 to January 15th 2008) that took place in one of the Iranian district and focused on severe injuries (leading to hospitalization over six hours or death). About 100 community health workers (Behvarzes) collected data according to a special assignment. They used a pre-determined form (a logbook) for data collection on injuries of various causes, including falls. At the end of data collection Behvarzes were asked, by questionnaire, about injury prevention measures and barriers in the community.</td>
</tr>
<tr>
<td><strong>Results:</strong> A total of 23 severe fall injuries (two fatal) were reported during the follow-up period with an annual estimated incidence rate of 8/10 000 (95% CI: 6-11). The incidence rate of severe falls was significantly higher among males than females (12/10 000 vs. 3/10 000 person-years). Fall incidence rates was also higher among people 65 years and over (24/10 000 person-years). Severe falls led commonly to fractures and lower limb was the most common single body region. Most falls were from height, mainly from roof and tree, and about half were work-related. The injury analyses revealed that the Behvarzes often considered that the adoption of safe behavior/practice could help preventing fall injuries (17 out of 23). Their post follow-up reflection on fall prevention indicates that education, provided by them could help prevent fall injuries (71 out of 87) and so could environmental improvement, people training, instruction, cooperation and consultation by other performers in this field. Also the barriers or risk factors for fall injury prevention identified related mostly to human factors (for all 23 cases) followed by physical environmental factors. At the end of the follow-up, however, they identified several physical environmental factors (44 out of 87), followed by social and legal environmental factors, and then, individual factors.</td>
</tr>
<tr>
<td><strong>Conclusion:</strong> Community health workers can provide a variety of suggestion for fall injury prevention and highlight potential barriers to their implementation among their catchment area.</td>
